Climbing AI Coach

Concept Video

Owen Kang, Jiemi Niu, Yulin Yu

Name: 3B (Bouldering Beta Buddy)

How did we land on the name?

We wanted a name the signals climbing beta, video-based learning, community comparison, and personal coaching.

1. Bouldering - We especially narrowed down to bouldering, which requires the most technique, balance, and brain.
2. Beta - The specific, actionable information, advice, or moves required to complete a climbing route.
3. Buddy - Getting help from our friend AI

One-liner Value Proposition

Providing a community where users can find useful videos and suggestions from others and get personalized suggestions from AI trained with data provided by users

Problem / Solution overview

primary user: Alex & Jackson (Climber training in busy gyms.)

What’s the Problem?

Climbers get stuck and want better beta + technique feedback but mid-climb feedback breaks focus/flow, and existing solutions either require gym-installed cameras or have unreliable personal filming issues

What’s the Solution?

A video-based AI coach that works in any gym, lets you record easily, then delivers fast post-climb insights + compare-your-beta vs community patterns, while learning your personal style over time.

Market Research

SPOT

Gym-installed cameras
provide real-time user behavior analysis and track the frequency (probability) of reaching each hold,

What works for out problem?

- Real-time behavior analysis; route difficulty and hold success rates.
- Lets users compare performance patterns.

What doesn't work?

Not installed in every climbing gym, so it's only applicable at specific climbing gyms.

Implication for our concept

We keep the community-level analytics idea, but avoid infrastructure lock-in by using personal recording and shared route database.

Belay AI

personal camera body tracking

What works for out problem?

Provides detailed information about my climb.

What doesn’t work?

Because it’s a personal camera, other people might walk in front of it or obstacles might block the view, causing me to miss some of the moves.

Implication for our concept

We design for gym reality, quick setup, stable angle guidance, and multi-attempt aggregation.

climbing.ai

When a climber uploads their video, AI analyzes their height, physical characteristics, and gender, and then visualize.

What works for out problem?

Provides visualized answers, incorporates my physical characteristics.

What doesn’t work?

Because it uses a personal camera, other people passing by or obstacles may cause the system to miss movements.

Implication for our concept

We combine body-aware visualization with community beta comparison.

comparison matrix

Task

Moderate-2

The user finds video from others and see the beta from on that route.

Why?

Even a shy climber can easily look at how others behave on the route and find videos online

Need to be done: timestamps for the video...

Moderate-1

The user learn from some general suggestions for that route/similar ones

Why?

Taking effort to decide which suggestion make sense for him, and apply these suggestions in next try

Need to be done: timestamps for the video...

Moderate-2

Uploads his video and gets feedback from AI

Why?

Posting videos takes effort, some users may not want to upload their own videos

Need to be done: timestamps for the video...

Complex

Getting more personalized suggestions overtime

Why?

General suggestions are enough for those "not-powered customers", they don't have enough motivation for doing that; keeping posting videos(for AI to learn about the customer) is hard as well

Need to be done: timestamps for the video...

Storyboarding

Complex

Getting more personalized suggestions overtime

Why?

General suggestions are enough for those "not-powered customers", they don't have enough motivation for doing that; keeping posting videos(for AI to learn about the customer) is hard as well

Need to be done: timestamps for the video...

THANK YOU

Any questions?
